Disclaimer:

While I'm reasonably confident about the contents of this talk, there is the very distinct possibility that I've got things wrong. See the list of references/sources at the end for places where you can get more information

THE STANDARD MODEL

	Fermions			Bosons		
Quarks	u up	c charm	t top	γ photon	Force carriers	
	d down	s strange	b bottom	Z Z boson		
Leptons	ν_e electron neutrino	ν_μ muon neutrino	ν_τ tau neutrino	W W boson		
	e electron	μ muon	τ tau	g gluon		
			Higgs [*] boson			

*Yet to be confirmed

Source: AAAS

Figure: Standard Model of Physics

- ▶ Neutrinos are nearly massless
- ▶ Only interact via Weak field interactions
- ▶ On average, $10^{16} \text{m}^{-2} \text{s}^{-1}$ at the Earth's surface

- ▶ Neutrinos are nearly massless
- ▶ Only interact via Weak field interactions
- ▶ On average, $10^{16} \text{m}^{-2} \text{s}^{-1}$ at the Earth's surface
- ▶ But only 3 neutrinos will interact with your body over your lifetime, on average
- ▶ → Neutrino experiments tend to be difficult!

- ▶ Neutrinos are nearly massless
- ▶ Only interact via Weak field interactions
- ▶ On average, $10^{16} \text{m}^{-2} \text{s}^{-1}$ at the Earth's surface
- ▶ But only 3 neutrinos will interact with your body over your lifetime, on average
- ▶ → Neutrino experiments tend to be difficult!
- ▶ To add to that, neutrinos 'oscillate' from one type to another over time, so what you end up with is not necessarily what you started with

- ▶ Collaboration of physicists from across the world
- ▶ Neutrinos fired at Gran Sasso by CERN
- ▶ Detector at Gran Sasso
- ▶ Sensitive timing equipment at each end

Figure: The “Particle Cannon”, aimed at Gran Sasso

- ▶ The main aim is to observe tau-neutrinos from the oscillation of muon-neutrinos
- ▶ One of the other possible experiments is to measure the time of flight between CERN and Gran Sasso

- ▶ Based on measurements over 3 years (2009,2010,2011), the distance was measured to be 730km
- ▶ Each packet of neutrinos sent from CERN was recorded, and the profiles matched to the corresponding bunches detected at Gran Sasso
- ▶ The result issued in September indicated that neutrinos were arriving sooner than they would if they travelled at c
- ▶ The 'anomaly' was calculated as $60.7 \pm 6.9(stat.) \pm 7.4(sys.)$ ns
(Statistical and Systematic errors respectively)

What did they get wrong?

Possibilities:

- ▶ Clocks weren't synced right
- ▶ Error analysis was too simplistic
- ▶ Difference between expected and actual neutrino production

What did they get wrong?

Possibilities:

- ▶ Clocks weren't synced right
- ▶ Error analysis was too simplistic
- ▶ Difference between expected and actual neutrino production
- ▶ And so on

Timing system:

- ▶ The master clocks were synced to each other, then transported to the experiment sites.
- ▶ Calibrated by Swiss Metrology Institute (METAS) and verified by the German Metrology Institute PTB

The error analysis saw a lot of attention when the paper was published - seems to be fine

The best explanation I've found suggests that OPERA may not have allowed for the motion of the GPS satellites. This would add an error of $\sim 64\text{ns}$, which would make the results consistent with known physics.

Any Questions?
